Overview of Foundation Medicine Oncomine CPT

Foundation Medicine Oncomine Comprehensive Panel Test (CPT) is a cutting-edge genomic profiling assay designed to detect a wide array of genetic alterations associated with various cancers. This test integrates Foundation Medicine's extensive cancer genomics expertise with the Oncomine platform's advanced sequencing technology. The aim is to provide a comprehensive molecular profile that includes mutations, copy number variations, gene fusions, and other genomic events. Foundation medicine oncomine cpt is especially valuable for identifying clinically actionable mutations that can guide the selection of targeted therapies or inform clinical trial eligibility.

What is Foundation Medicine?

Foundation Medicine is a leader in molecular diagnostics, specializing in comprehensive genomic profiling of tumors. Their assays analyze hundreds of cancer-related genes to uncover alterations that influence tumor behavior and treatment response. Foundation Medicine's tests are widely recognized for their accuracy, reliability, and clinical utility.

Introduction to Oncomine CPT

The Oncomine Comprehensive Panel Test is a next-generation sequencing (NGS) assay that targets a broad spectrum of genetic aberrations in solid tumors. It is designed to detect single nucleotide variants (SNVs), insertions and deletions (indels), copy number alterations (CNAs), and gene fusions, providing a detailed molecular portrait of the cancer.

Technical Aspects and Methodology

The foundation medicine oncomine cpt utilizes sophisticated NGS technology to analyze tumor DNA and RNA extracted from biopsy or surgical specimens. This section explains the technical workflow and the types of genomic alterations detected by the test.

Next-Generation Sequencing Technology

NGS forms the core of the Oncomine CPT, allowing simultaneous sequencing of multiple genes with high sensitivity and specificity. The test sequences both DNA and RNA to capture a comprehensive set of alterations, including gene fusions that are often missed by DNA-only assays.

Genomic Alterations Detected

Foundation medicine oncomine cpt detects various genetic changes, including:

- Single Nucleotide Variants (SNVs)
- Insertions and Deletions (Indels)
- Copy Number Alterations (CNAs)
- Gene Fusions and Rearrangements
- Microsatellite Instability (MSI) and Tumor Mutational Burden (TMB)

Sample Requirements and Processing

The test requires formalin-fixed, paraffin-embedded (FFPE) tissue samples, which are routinely collected in clinical oncology. Foundation Medicine's laboratory processes these samples using stringent quality control measures to ensure reliable and reproducible results.

Clinical Applications in Oncology

Foundation medicine oncomine cpt plays a crucial role in precision oncology by enabling personalized treatment decisions based on the tumor's molecular profile. This section explores key clinical scenarios where the test is instrumental.

Targeted Therapy Selection

By identifying actionable mutations, foundation medicine oncomine cpt helps oncologists select targeted therapies that specifically inhibit oncogenic drivers. For example, detection of EGFR mutations or ALK fusions in lung cancer patients can guide the use of tyrosine kinase inhibitors.
